Revised 20 May 2003

We construct an explicit representation of the algebra of local diffeomorphisms of a manifold with realistic dimensions. This is achieved in the setting of a general approach to the (quantum) dynamics of a physical system which is characterized by the fundamental role assigned to a basic underlying symmetry. The mathematical formalism developed addresses the relevant gravitational notions by means of the addition of some extra structure. The specific manners in which this is accomplished, together with their corresponding physical interpretation, lead to different gravitational models. Distinct strategies are in fact briefly outlined, showing the versatility of the present conceptual framework.

Keywords: Diffeomorphism algebra; anomalies; quantum gravity.

PACS numbers: 02.20.Tw, 04.60.-m, 03.65.Fd

1. Introduction

A model for space–time dynamics in 1 + 1-dimensions was introduced in Ref. 1. The present paper studies the necessary extension to realistic dimensions of the involved mathematical structures together with their physical implications.

The original work was conceived as a directly quantum formulation of the physical system, rather than a quantization of a previously devised classical theory. The rationale for such a construction was the fundamental role attached to the notion of symmetry in the characterization of the dynamics. Specifically, group cohomology governing the structure of the central extensions became the guiding principle in the identification of those dynamical degrees of freedom building the phase space. The

∗Work partially supported by the DGICYT.
choice of the abstract Virasoro algebra as the basic symmetry led to a quantum
theory addressing two-dimensional Polyakov gravity\(^2\) at the semi-classical level. The main achievements of that particular model were the recovery of a space–time
notion out of the symmetry itself without its explicit introduction into the scheme
from the very beginning, on the one hand, and the gain of dynamical character
by some diffeomorphisms thus entailing a quantum breakdown of their associated
gauge invariance, on the other hand.

When extending this kind of analysis to systems with support on higher-
dimensional space–times, we can identify two conceptually different levels of
generalization. The first one, structural in nature, deals with the construction of
the mathematical formalism supporting the new model. We shall approach this
problem by firstly identifying a Lie algebra which properly generalizes the Vira-
soro one, and then constructing the quantum and semi-classical dynamics that it
provides. This task will be achieved by using the so-called Group Approach to
Quantization (GAQ),\(^3\) as was the case in Ref. 1. The second level refers to the
physical interpretation of that mathematical formalism. The intuition provided in
the two-dimensional case by the Polyakov action will be definitively lost in the
higher-dimensional model, and therefore new links with a metric notion will be
needed. Our specific goal at this level will be the implementation of the quantum
breakdown of diffeomorphism invariance at the quantum level, perhaps the most
fundamental feature in this approach. With regard to the space–time recovery from
the group structure, we shall dwell only on the most simple situation in which no
critical conditions in the cohomology parameters (i.e. anomalies) occur. Adopting
this attitude, we are essentially leaving this specific issue open for future research.

Apart from the above-described line of reasoning, the present considerations
make useful contact with the research programme initiated in Ref. 4. A novel
approach to the problem of mixing space–time and internal gauge interactions
was proposed with support on a revisited gauge principle, which implies a non-
trivial interplay between the corresponding local current algebras. The restriction
in these works to a Particle-Mechanical setting freezes the dynamics corresponding
to those local currents, thereby obscuring their relevance. Nevertheless, these
intrinsic dynamics prove to be an essential ingredient in the GAQ treatment of
gauge interactions\(^5,6\) at the field level (see below). In particular, gravitational inter-
action is addressed in Ref. 4 by making local the translation subgroup,\(^7\) which
leads to a current algebra isomorphic to that of local diffeomorphisms (see Sub-
sec. 2.2). Therefore the dynamics behind this diffeomorphism algebra provides an
intermediate step fundamental in the understanding of the proposed interaction
mixing for field degrees of freedom, constituting a secondary but significant goal of
the present paper.

The structure of the paper is as follows. Section 2 is divided in two subsections.
The first briefly presents the fundamentals of the GAQ, the technique we use to
construct the dynamical system out of a Lie symmetry. In the second, the rigour
of the presentation is significantly relaxed in order to motivate the relevant algebra
we are using as a starting point. It also includes a brief explanation on the role of local gauge groups in the GAQ treatment of gauge theories. Section 3 recovers a more formal style and includes our main results, i.e. the dynamics associated with the Lie algebra proposed in the previous section. This will be done both at the semi-classical and quantum level. In particular, a maximum-weight representation of an (noncentrally) extended diffeomorphism algebra will be explicitly constructed. Section 4 contains the corresponding physical discussion, while the conclusions will be presented in Sec. 5.

2. General Setting

2.1. Technical formalism: GAQ

We briefly describe the basics of the Group Approach to Quantization (GAQ), a formalism that surpasses its role as a technical device, deeply influencing and guiding the conceptual understanding of the physical dynamics construction.

The starting point is a Lie group $\hat{G}$ with a U(1)-principal bundle structure with base $G$. This bundle possesses a connection one-form $\Theta_{PC}$, i.e. the (pre-)contact form of time-dependent dynamics. This connection also plays a main role in the quantization procedure, and is (naturally) selected among the components of the left-invariant, Lie-algebra valued, Maurer–Cartan one-form, in such a way that $\Theta(\Xi) = 1$ and $\Theta(\tilde{X}_L^i) = 0$, where $\Xi$ is the vertical (or fundamental) vector field of the principal bundle and $\tilde{X}_L^i$ are the rest of the independent left-invariant generators in a basis of the Lie algebra.

Taking $\hat{G}$ as a central extension of $G$ by U(1) (the tilde will denote extended objects throughout), we consider the space of complex functions $\Psi$ on $\hat{G}$ satisfying the U(1)-equivariance condition, i.e. $\Psi(\zeta \ast g) = \zeta \Psi(g)$, $\zeta \in U(1)$, $g \in \hat{G}$. On this space, the left translations on $\hat{G}$ (generated by right-invariant vector fields $\tilde{X}_R^j$) realize a representation of the group which is in general reducible. Right translations, generated by left-invariant vector fields $\tilde{X}_L^i$, do commute with the left ones on any Lie group. Therefore, certain subgroups, called polarization subgroups $G_P$, can be chosen to perform a reduction of the representation through the so-called polarization conditions, following the language of Geometric Quantization, which are implemented by left-invariant vector fields. This defines a reduced subspace of wave functions, $\mathcal{H}$, satisfying $\Psi(g \ast G_P) = \Psi(g)$ (or infinitesimally $L_{\tilde{X}_L} \Psi = 0$, $\forall \tilde{X}_L \in \mathcal{G}_P$, where $\mathcal{G}_P$ is the Lie algebra of $G_P$).

In the finite-dimensional case, the Hilbert space structure on the space of wave functions is provided by the invariant Haar-like measure constructed from the exterior product of the left-invariant canonical form components, $\Omega^L \equiv \theta^{L_0^1} \wedge \theta^{L_0^2} \wedge \cdots$. On the reduced space $\mathcal{H}$ (at least for the case of first-order polarizations), the existence of a quasi-invariant measure is granted, since the wave functions have support on $G/G_P$, which is a homogeneous space. However we shall deal here with an infinite-dimensional symmetry whose associated representation space
is given by an orbit of the group through a (unique) vacuum state. This allows the introduction of a Hilbert product by fixing the normalization of that vacuum and imposing a rule of adjointness for the basic operators.

The classical theory for the system is easily recovered by defining the Noether invariants as \( \mathcal{N}_g \equiv i_{\xi} \Theta \). They are in fact invariant under the evolution generated by vector fields inside \( \mathcal{G}_\Theta = \text{Ker} \Theta \cap \text{Ker} d\Theta \), which define the generalized equations of motion. The classical phase space is given by \( G/G_\Theta \) (see Ref. 3 and references therein). A Poisson bracket can be introduced (defined by \( d\Theta \)) in such a way that the Noether invariants generate a Lie algebra isomorphic to that of \( \mathcal{G} \).

### 2.2. Starting algebra

The choice of the starting Lie algebra, defining the fundamental symmetry underlying the system, will be guided by the attempt to implement our basic goals.

#### Generalization of Virasoro algebra

Firstly, the generalization of the Virasoro algebra, together with the desire to analyze a potential physical breakdown of the diffeomorphism invariance in realistic space–time dimensions, suggests the adoption of the local diffeomorphism algebra of a \( d \)-dimensional manifold \( M \) (\( d \geq 2 \)) as a natural departure point. This algebra, denoted by \( \text{Vect}(M) \) in Ref. 9, is simply given by vector fields on \( M \) with the natural Lie product,

\[
[L_{\mu}^{(m)}, L_{\nu}^{(n)}] = n_{\mu} L_{\nu}^{(m+n)} - m_{\nu} L_{\mu}^{(m+n)}.
\]

The cohomological analysis of this algebra rules out the possibility of nontrivial central extensions (\( d \geq 2 \)), which is not a fundamental drawback for the construction of the corresponding dynamics, as will be explicitly shown at the end of this section. Noncentral extensions must be considered if we wish to enrich the dynamics, entailing the introduction of new fields in the model. A particular class of these extensions, the tensorial ones, are studied and classified in Refs. 10 and 11 providing a variety of possibilities from which to choose. Here we shall consider the simplest extension, represented by a generator \( S^\epsilon(m) \). This option constitutes in fact a direct generalization of the cubic cocycle of the Virasoro algebra, reducing to it in the one-dimensional case (in precise terms, a closure condition must be imposed to \( S^\epsilon(m) \)). The Lie algebra is given by

\[
[L_{\mu}^{(m)}, L_{\nu}^{(n)}] = n_{\mu} L_{\nu}^{(m+n)} - m_{\nu} L_{\mu}^{(m+n)}
- m_{\nu} n_{\mu}(m_\rho - n_\rho) S^\epsilon(m+n),
\]

\[
[L_{\mu}^{(m)}, S^\epsilon(n)] = n_{\mu} S^\epsilon(m+n) + \delta^\epsilon_\mu m_\rho S^\epsilon(m+n).
\]
Contact with the interaction mixing problem

Secondly, for our purpose of relating this algebra to the works in Ref. 4, let us briefly sketch a comparison between the ways in which field degrees of freedom are handled in the standard approach to (Yang–Mills) gauge theories and in GAQ.

In an oversimplified version of the former, which omits all technical and conceptual subtleties, the field degrees of freedom are constructed in terms of the components $A^a_\mu$ (gauge fields) of a connection on a principal bundle, with $U$ as the structure group and the space–time $M$ as its base. These modes couple to the matter degrees of freedom, living on an associated vector bundle, by means of the so-called \textit{minimal coupling}, technically implemented by replacing the partial derivatives in the matter Lagrangian with a covariant derivative defined in terms of the connection (very roughly, $\partial_\mu \rightarrow (\partial_\mu + A_\mu)$). The Lagrangian giving the intrinsic dynamics of the gauge fields is defined as a function of the curvature $F_{\mu\nu}$ of the connection form.\footnote{112} This description of the system is overcomplete since not all the field degrees $A^a_\mu$ are in fact physical. Two connections $A'_\mu$ and $A_\mu$ are physically equivalent if they are related by the action of the gauge group (locally identifiable with $\text{Map}(M, U)$), $A'_\mu = u^{-1} A_\mu u + u^{-1} du$. Taking quotient by the orbits of the gauge group, we obtained the reduced or physical phase space.

The whole spirit and structural description changes in the GAQ. Instead of a space of field degrees of freedom parametrized by $A_\mu$, on which a Lagrangian $L$ is defined and which must be reduced according to the action of a given gauge group, in GAQ, all these elements must be merged into a single centrally-extended group $\tilde{G}$. The dynamics, as well as the identification of the physical degrees of freedom, must follow from the algorithm described in the previous subsection. There is no obvious way of endowing the connection components $A^a_\mu$ with a group law structure, closing, in addition, a Lie symmetry with the gauge group $\text{Map}(M, U)$. An explicit solution to this problem, not necessarily unique, is presented in Refs. 5 and 6. The price we must pay for closing such a unified Lie structure is the loss of a clean distinction at the group law level between the degrees of freedom corresponding to the gauge fields (the “connections”) and the parameters corresponding to the gauge group. These modes are subtly intertwined in such a way that a transfer of dynamical content occurs between them. To fix ideas, we comment on the simplest case of a local $U(1)$ gauge group in the unified treatment of the electromagnetic and Proca fields.\footnote{5} Working in momentum space and parametrizing the gauge fields by $a_\mu(k)$ and $a^*_\mu(k)$, and the $U(1)$ parameters by $\phi(k)$ and $\phi^+(k)$, the corresponding group law implies at the Lie algebra level the following commutators,

\begin{align}
\left[ \tilde{X}^L_{a^*_\mu(k)}, \tilde{X}^L_{a^*_{\mu}(k')} \right] &= i\eta^{\mu\nu} \Delta_{kk'} \Xi, \quad \left[ \tilde{X}^L_{\phi^+(k)}, \tilde{X}^L_{\phi^+(k')} \right] = ik^2 \Delta_{kk'} \Xi, \\
\left[ \tilde{X}^L_{a^*_\mu(k)}, \tilde{X}^L_{a^*_{\mu}(k')} \right] &= k^\mu \Delta_{kk'} \Xi, \quad \left[ \tilde{X}^L_{a^*_\mu(k)}, \tilde{X}^L_{\phi^+(k')} \right] = k^\mu \Delta_{kk'} \Xi,
\end{align}

(4)
where $\Delta_{k k'} = 2k^0 \delta^3(k - k')$ is the generalized delta function on the positive sheet of the mass hyperboloid. The second commutator in the first line explicitly shows the nonempty symplectic content of $(k)$, whereas those in the second line imply the above-mentioned mixing between the $a_\mu(k)$ and $\phi(k)$ variables. The diagonalization of the cocycle when determining the canonical symplectic variables entails the transfer of dynamical content between modes. The generators playing the role of authentic gauge transformations in this setting (they leave the reduced physical phase space invariant pointwise) are in fact,

\[
\hat{X}_{c l}(k) = \hat{X}_{\phi(k)} + ik_\mu \hat{X}_{a_\mu(k)},
\]

which imply the equivalence condition,

\[
a_\mu(k) \sim a_\mu(k) + ik_\mu c(k), \quad \phi(k) \sim \phi(k) + c(k)
\]

together with its Hermitian conjugate, where $c(k)$ is the evolution parameter of the $\hat{X}_{c l}(k)$ vector field. They simply represent the momentum version of the standard gauge transformations.

The only aim in the preceding discussion was that of underlining the importance of a good understanding of the (abstract) intrinsic dynamics associated with the local gauge group, determined by its extensions, when we address gauge theories in the GAQ formalism.

With respect to the idea of mixing external and internal interactions as described in Ref. 4, the relevant gauge invariance groups were determined from the local current algebras $\mathcal{F}(M) \otimes \mathcal{G}$, where $\mathcal{F}(M)$ is the real functions on $M$ and $\mathcal{G}$ the Lie algebra of the rigid part of the gauge group. Choosing a realization $\{X_a\}$ for the latter, we have:

\[
[f \otimes X_a, g \otimes X_b] = (f L_{X_a} g) \otimes X_b - (g L_{X_b} f) \otimes X_a + (fg) \otimes [X_a, X_b].
\]

The gravitational interaction was addressed by making the rigid translation group local. Choosing $\partial_\mu$ as a realization for its generators, the corresponding current algebra turns out to be isomorphic to the local diffeomorphism algebra (1). Therefore, in the study of Gravity as a gauge interaction with a gauge group obtained by making the space–time translations local (Ref. 7 and first part of IIIA in Ref. 13), the analysis of the intrinsic dynamics derived from the diffeomorphism algebra plays a fundamental role in a GAQ setting. The modes $L_\mu(m)$ are just the analogue to $\phi(k)$ in the electromagnetic case. Of course, it represents only an intermediate step, since the gauge fields analogue to $a_\mu(k)$ should be introduced consistently at a second stage.

The mixing of gravitational and electromagnetic interactions in Ref. 4 occurred through the weaving together the corresponding current algebras. In order to consider such a possibility, we introduce the new generators $f \otimes \Xi$ corresponding to the
local U(1). In the momentum space we are dealing with, their expression is $A(m)$ and the new commutators are given by

$$
[L_\mu(m), A(n)] = n_\mu A(m+n), \\
[A(m), A(n)] = (n_\mu - m_\mu)S^\rho(m+n),
$$

(8)

where we have taken advantage of the possibility of introducing a new (and independent) extension in the U(1) sector implemented by the already present $S^\rho(m)$ generators. Therefore, our starting algebra is given by commutators (3) + (8).

**Central extensions**

Since we need a U(1)-centrally extended group in order to employ the GAQ, the starting Lie algebra should present central terms in the commutators. The central terms that cannot be eliminated by a linear change of basis in the Lie algebra are controlled at the group level\(^a\) by the nontrivial two-cocycles in the second cohomology group of the nonextended Lie group $G$, $H^2(G, U(1))$. But these are not the only cocycles capable of creating dynamics. In fact, and it is especially important in the case of Lie groups with trivial cohomology, those coboundaries $\xi_\lambda$ generated by a function on the group $\lambda$ such that $\frac{\partial \Lambda}{\partial g} \bigg|_{g=c} \neq 0$ lead to dynamics on phase spaces which are symplectomorphic to the coadjoint orbits of the group. Of course, these coboundaries generate central terms at the algebra level that could be eliminated by linear changes, so they are consistently trivial from the standpoint of the Lie structure. Nevertheless, they have crucial consequences on the polarization conditions and, therefore, at the representation level. We can reverse the reasoning and consider that, once the algebra has been (trivially or not) extended by a central U(1) group, a linear change in the algebra involving the central generator will be associated with one of those coboundaries creating dynamics. These subclasses inside $H^2(G, U(1))$ were first introduced in Ref. 14 in association with some coboundaries $\xi_\lambda$, which become nontrivial cocycles $\xi_c$ after an Inonu–Wigner contraction takes place, and have been fully studied in connection with coadjoint orbits in Ref. 15. The simplest example of the latter is the Poincaré group whose pseudo-cohomology goes to the true cohomology of the Galilei group.\(^{16}\) For finite-dimensional semi-simple groups, pseudo-cohomology is also related to the Cech cohomology of the generalized Hopf fibrations by the Cartan subgroups $H, G \to G/H.\(^{17}\)$

The algebra (3) + (8) we are using as the starting point does not present the central extension structure we need in order to derive the dynamics. In fact, no nontrivial extensions exist when the space–time dimension is higher than one. Therefore, we take advantage of the above-discussed pseudo-cohomology to add a new

\(^a\)In this general remark, we shall not address the differences between Lie algebra and Lie group cohomology.
central generator $\Xi$ to the Lie algebra in a direct-sum way. We then perform the linear change

$$A(m) \mapsto A(m) + \alpha \delta(m)\Xi,$$

$$S^\alpha(m) \mapsto S^\alpha(m) + C^\alpha \delta(m)\Xi,$$

$$L_\mu(m) \mapsto L_\mu(m) + \tilde{C}_\mu \delta(m)\Xi,$$

which will give rise to one of the dynamically nontrivial coboundaries, after exponentiation.

3. Dynamics

As we have seen, the starting point for the whole construction is the explicit group law of the Lie symmetry defining the physical system. In the previous section we worked only at the algebra level. Thus, the first step now is to exponentiate it to a finite group law. This entails the complications derived from dealing with infinite-dimensional Lie algebras. We shall face this difficulty by using a perturbative order-by-order construction of a formal group law, as described in Ref. 17.

With the use of an index $\mu(m)$ for $L_\mu(m)$, $\tilde{\mu}(m)$ for $S^\mu(m)$, $m$ for $A(m)$ and $\varphi$ for $\Xi$, the structure constants in this basis are (there is a harmless global redefinition by a minus sign related to the particular exponentiation technique we are going to employ):

$$C^\rho_{\mu(n)\nu(n)} = -(n_\mu \delta^\rho_\nu - m_\nu \delta^\rho_\mu)\delta(m + n - r),$$

$$C^\rho_{\mu(n)\nu(n)} = m_\mu n_\nu (m_\rho - n_\rho)\delta(m + n - r),$$

$$C^\rho_{\mu(n)\nu(n)} = -[m_\mu n_\nu (m_\rho - n_\rho) C^\rho + (n_\mu \delta^\rho_\nu - m_\nu \delta^\rho_\mu) \tilde{C}_\rho] \delta(m + n),$$

$$C^\rho_{\mu(n)\nu(n)} = -(n_\mu \delta^\rho_\nu - m_\nu \delta^\rho_\mu) \delta(m + n - r),$$

$$C^\rho_{\mu(n)\nu(n)} = -(n_\mu \delta^\rho_\nu - m_\nu \delta^\rho_\mu) C^\rho \delta(m + n + n),$$

$$C^\rho_{\mu(n)\nu(n)} = -(n_\mu - m_\nu) \delta(m + n - r),$$

$$C^\rho_{\mu(n)\nu(n)} = -(n_\mu - m_\nu) C^\rho \delta(m + n),$$

$$C^\rho_{\mu(n)\nu(n)} = -\alpha n_\mu \delta(m + n).$$

We use them to construct a formal group law, $g'' = g' \ast g$, up to the third-order in the group variables. We associate the variable $l^\mu(m)$ with the generator $L_\mu(m)$, $s^\mu(m)$ with $S^\mu(m)$, $a(m)$ with $A(m)$ and $\varphi$ with $\Xi$, obtaining

$$l^{\rho}(r) = l^{\mu}(r) + l^{\nu}(r) + \frac{1}{2} C^\rho_{\mu(n)\nu(n)} l^{\mu}(m) l^{\nu}(n) + \frac{1}{8} C^\rho_{\mu(n)\nu(n)} C^\rho_{(q,s)(q,s)} l^{\mu}(n) l^{\nu}(q) l^{\sigma}(s) + \cdots,$$
\[ s''(r) = s^p(r) + s^l(r) + \frac{1}{2} C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) l^\nu(n) \]
\[ + C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) s^v(n) + \frac{1}{2} C_{mn}^{\rho(r)} a'(m) a(n) \]
\[ + \frac{1}{2} \left[ C_{\nu(n)\mu(m)}^{\rho(r)} l^\mu(m) C_{\gamma(q)\sigma(s)}^{\rho(r)} + \frac{1}{2} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} \right] l^\nu(n) l^\gamma(q) l^\sigma(s) \]
\[ + C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) l^\gamma(q) l^\sigma(s) \]
\[ + \frac{1}{2} C_{mn}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} s^\sigma(s) + \frac{1}{2} C_{mn}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) l^\gamma(q) a'(n)a(s) \right] + \cdots, \]
\[ a''(p) = a'(p) + a(p) + C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) l^\nu(n) a(n) \]
\[ + \frac{1}{2} C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) l^\nu(n) a(n) \]
\[ + \frac{1}{2} \left[ C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) l^\gamma(q) l^\sigma(s) \]
\[ + C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) l^\gamma(q) l^\sigma(s) \]
\[ + \frac{1}{2} C_{mn}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) s^\sigma(s) \]
\[ + \frac{1}{2} C_{mn}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) l^\gamma(q) a(s) + \frac{1}{2} C_{mn}^{\rho(r)} C_{\gamma(q)\sigma(s)}^{\rho(r)} l^\nu(n) s^\sigma(s) \right] l^\nu(n) a'(r) a(s) + \cdots. \] (11)

Using this, we compute the left-invariant vector fields, \[ \dot{X}_{(k)}^{L}(g) = \frac{\partial}{\partial g^r \varphi} \left. \hat{X}_{(k)}^{L}(g) \right|_{g=e^{g'},g=g} \]
\[ \frac{\partial}{\partial \gamma^r \varphi}, \text{ yielding,} \]
\[ \dot{X}_{(t)}^{L} = \frac{\partial}{\partial \gamma^r(t)} + \left\{ \frac{1}{2} C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) + \frac{1}{8} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\tau(t)}^{\rho(r)} l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial \rho^r} \]
\[ + \frac{1}{2} C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) + \frac{1}{8} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\tau(t)}^{\rho(r)} l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial \gamma^r} \]
\[ + \frac{1}{2} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\tau(t)}^{\rho(r)} l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial \rho^r} \]
\[ \dot{X}_{(t)}^{S} = \frac{\partial}{\partial \gamma^r} + \left\{ C_{\mu(m)\nu(n)}^{\rho(r)} l^\mu(m) + \frac{1}{2} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\tau(t)}^{\rho(r)} l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial \rho^r} \]
\[ + \left\{ C_{\nu(n)\mu(m)}^{\rho(r)} l^\mu(m) + \frac{1}{2} C_{\nu(n)\mu(m)}^{\rho(r)} C_{\gamma(q)\tau(t)}^{\rho(r)} l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial \xi^r} \]
\[
\tilde{X}_a(t) = \frac{\partial}{\partial u(t)} + \left\{ C_{\mu(m)}^\rho(t) l^\rho(m) + \frac{1}{2} C_{\nu(n)m}^\gamma C_{\gamma(q)\nu(n)}^\mu l^\nu(n) l^\gamma(q) + \cdots \right\} \frac{\partial}{\partial u(r)} \\
+ \left\{ \frac{1}{2} C_{m(t)}^\mu a(m) + \frac{1}{4} C_{q(m)}^\nu C_{\nu(n)t}^\mu l^\nu(n) a(q) + \cdots \right\} \frac{\partial}{\partial s^\mu(p)} \\
+ \left\{ \frac{1}{2} C_{\rho(m)}^\nu a(m) + C_{\rho(m)t}^\mu l^\mu(m) + \frac{1}{2} C_{\rho(n)m}^\gamma C_{\gamma(n)t}^\mu l^\rho(r) l^\nu(n) \\
+ \frac{1}{4} C_{nm}^\mu C_{\rho(t)}^l l^\rho(r) a(n) + \cdots \right\} \frac{\partial}{\partial \phi},
\]

\[\tilde{X}_\phi = \frac{\partial}{\partial \phi}, \quad (12)\]

and also the right-invariant vector fields
\[
\tilde{X}_R^{(1)}(g) = \frac{\partial g^{\mu}(g^t,g)}{\partial g^{(0)}} \bigg|_{g^t=e,g^0=g} \frac{\partial}{\partial g},
\]

\[\tilde{X}_R^{(2)}(g) = \frac{\partial}{\partial s^\rho(t)} + \cdots, \quad (13)\]

\[\tilde{X}_R^{(n)}(g) = \frac{\partial}{\partial a(t)} + \frac{1}{2} C_{\rho(n)}^\mu a(n) \frac{\partial}{\partial s^\mu(r)} + \frac{1}{2} C_{\rho(n)}^\mu a(n) \frac{\partial}{\partial \phi} + \cdots, \quad (13)\]

\[\tilde{X}_R^{\phi} = \frac{\partial}{\partial \phi}.\]

Analogously, the quantization one-form, \( \Theta = \theta L(\varphi) = \frac{\partial g^{\mu}(g^t,g)}{\partial g^{(0)}} \bigg|_{g^t=g^0=g^{-1}} \frac{dg^k}{k} \) has the expression
\[
\Theta = \theta L(\varphi) = d\varphi + \left\{ -\frac{1}{2} C_{\mu(m)\nu(n)}^\rho l^\rho(m) + \left( \frac{1}{8} C_{\rho(r)\mu(m)}^\gamma C_{\gamma(q)\nu(n)}^\mu l^\nu(n) l^\gamma(q) \right) \right\} dl^\nu(n) \\
+ \left\{ -\frac{1}{2} C_{\mu(m)\nu(n)}^\rho l^\rho(m) + \frac{1}{2} C_{\rho(r)\mu(m)}^\nu C_{\gamma(q)\nu(n)}^\rho l^\rho(r) l^\gamma(n) \right\} ds^\nu(n)
\]
coordinates in the solution manifold. Up to the second order (inherited from the written in terms of the remaining (basic) Noether invariants, which can be used as Noether formalism.

Except for critical combinations of the pseudo-cohomology parameters (related to possible anomalies), which we are not going to focus on here, the simultaneous trajectories are

\[
N^G = i \dot{X}^G = \partial_a = \frac{1}{2} C^{\phi}_{\mu(m)} \frac{\partial}{\partial \phi} \quad \text{and denoted by} \quad \mathcal{G}_\Theta. \]

These vector fields are the generators of the generalized equations of motion, the classical trajectories being given by \( G/G_\Theta \). The Noether invariants under these classical trajectories are

\[
N^\gamma(t) = i \dot{X}^\gamma(t) \Theta = C^{\phi}_{\gamma(t)} \frac{\partial}{\partial \phi} \quad \text{and denoted by} \quad \mathcal{G}_\Theta. \]

Finally, the Noether invariants associated with the vector fields inside \( \mathcal{G}_\Theta \) can be written in terms of the remaining (basic) Noether invariants, which can be used as coordinates in the solution manifold. Up to the second order (inherited from the third order in the group law) we find

\[
N^\gamma(0) = \begin{cases} 
\frac{3}{4} \left( \frac{1}{2} C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \left( \frac{\partial}{\partial \phi} \right)^{-1} \left( C^{\phi}_{\rho(r)} = C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right) \\
- C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \\
\times \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right) \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \\
\times \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right) \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \left( C^{\phi}_{\rho(r)} \frac{\partial}{\partial \phi} \right)^{-1} \\
\end{cases}
\]
\[-C_{\alpha}^{\varphi}(a)q \left(C_{\alpha}^{\varphi}(a, q)\right)^{-1} C_{\alpha}^{\varphi}(n, q) \left(C_{\alpha}^{\varphi}(n', q')\right)^{-1} \]

\[+ \frac{1}{2} C_{\alpha}^{\varphi} C_{m}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\gamma}^{\varphi}(r)\right)^{-1} C_{n}^{\varphi}(q') \left(C_{\alpha}^{\varphi}(q')\right)^{-1} \]

\[\times \left(C_{\varphi}^{\varphi}(s)\right)^{-1} C_{\varphi}^{\varphi}(n', q') \left(C_{\alpha}^{\varphi}(n', q')\right)^{-1} - C_{\rho}^{\varphi}(r) C_{\mu}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\rho}^{\varphi}(r)\right)^{-1} \]

\[\times \left(C_{\varphi}^{\varphi}(s)\right)^{-1} C_{\varphi}^{\varphi}(n', q') \left(C_{\alpha}^{\varphi}(n', q')\right)^{-1} \right\} N_{n}^{\alpha}(n) N_{s}^{\alpha}(n') \]

\[+ C_{\rho}^{\varphi}(r) C_{\mu}^{\varphi} (C_{\gamma}^{\varphi}(0) \left(C_{\alpha}^{\varphi}(q)\right)^{-1} (C_{\alpha}^{\varphi}(a) C_{\gamma}^{\varphi}(q))^{-1} N_{s}^{\alpha}(n) N_{\alpha}(a) \]

\[+ \left\{- C_{\rho}^{\varphi}(r) C_{\mu}^{\varphi}(m) \left(C_{\gamma}^{\varphi}(q)\right)^{-1} \left(C_{\alpha}^{\varphi}(a)\right)^{-1} N_{s}^{\alpha}(n) N_{\alpha}(a) \right\} \]

\[-\frac{1}{2} C_{\alpha}^{\varphi} C_{m}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\gamma}^{\varphi}(r)\right)^{-1} (C_{\alpha}^{\varphi}(s))^{-1} C_{\gamma}^{\varphi}(q') \left(C_{\alpha}^{\varphi}(q')\right)^{-1} \]

\[+ \left(C_{\alpha}^{\varphi}(s)^{-1} C_{\alpha}^{\varphi}(q') \left(C_{\alpha}^{\varphi}(q')\right)^{-1} + C_{\rho}^{\varphi}(r) C_{\mu}^{\varphi}(m) \left(C_{\rho}^{\varphi}(r)\right)^{-1} (C_{\alpha}^{\varphi}(s))^{-1} \right\} \]

\[\times N_{s}^{\alpha}(n) N_{\alpha}(a) + \frac{1}{2} C_{\alpha}^{\varphi} C_{m}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\alpha}^{\varphi}(s)^{-1} (C_{\alpha}^{\varphi}(t)\right)^{-1} N_{s}^{\alpha}(t) N_{\alpha}(a) + \cdots, \]

\[N_{s}^{\alpha}(0) = \frac{1}{2} C_{\alpha}^{\varphi} C_{m}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\alpha}^{\varphi}(s)^{-1} (C_{\alpha}^{\varphi}(t)\right)^{-1} N_{s}^{\alpha}(t) N_{\alpha}(a) + \cdots, \]

\[N_{s}^{\alpha}(0) = \left\{- \frac{1}{4} \left(2 C_{\alpha}^{\varphi} C_{\gamma}^{\varphi}(0) + C_{\alpha}^{\varphi} C_{\gamma}^{\varphi}(0) + 2 C_{\rho}^{\varphi}(r) C_{\mu}^{\varphi}(m) \right) \]

\[\times \left(C_{\alpha}^{\varphi}(t)^{-1} \right)^{-1} C_{\alpha}^{\varphi}(q') \left(C_{\alpha}^{\varphi}(q')\right)^{-1} \left(C_{\alpha}^{\varphi}(m)\right)^{-1} \]

\[+ \frac{1}{2} C_{\alpha}^{\varphi} C_{m}^{\varphi} C_{\gamma}^{\varphi}(0) \left(C_{\alpha}^{\varphi}(t)^{-1} \right)^{-1} (C_{\alpha}^{\varphi}(n')\right)^{-1} \left(C_{\alpha}^{\varphi}(n')\right)^{-1} \]

\[\times \left(C_{\alpha}^{\varphi}(t)^{-1} \right)^{-1} \left(C_{\alpha}^{\varphi}(q')\right)^{-1} \right\} N_{s}^{\alpha}(t) N_{s}^{\alpha}(n') + \cdots \]
and is infinitesimally implemented by the right-invariant vector fields. To reduce
this representation, we must impose a polarization condition associated with a (left-
 invariant) polarization algebra \( G_P \), implying the selection of a particular class of
representations.

We shall implement the easiest polarization conceivable in this context. To do
so, we introduce the following notation: given a vector \( m \neq 0 \), let us call \( m_f \) the
first nonzero entry \( m_i \). For \( m = 0 \), let \( m_f = 0 \). Now we introduce the following
polarization:

\[
G_\Theta = \left\langle X_{\mu}(t_{f\leq 0}), X_{\nu}(t_{f\leq 0}), X_{\sigma}(t_{f\leq 0}) \right\rangle ,
\]

(18)
defining the polarization equations:

\[
X_{\mu}(t_{f\leq 0}) \Psi = 0 ,
\]

\[
X_{\nu}(t_{f\leq 0}) \Psi = 0 ,
\]

\[
X_{\sigma}(t_{f\leq 0}) \Psi = 0 .
\]

(19)

A general solution can be written as a linear combination:

\[
\Psi = A|0\rangle + \sum_{m(m_f \geq 0)} (A_{\mu(m)}|l^\mu(m)\rangle + A_{\bar{\nu}(m)}|s^\nu(m)\rangle + A_{\sigma(m)}|a(m)\rangle)
\]

\[
+ \sum_{m(m_f \geq 0)} (A_{\mu(m)\nu(n)}|l^\mu(m)|l^\nu(n)\rangle + A_{\mu(m)\bar{\nu}(n)}|l^\mu(m)|s^\nu(n)\rangle
\]

\[
+ A_{\mu(m)n}|l^\mu(m)|a(n)\rangle + A_{\bar{\nu}(m)n}|s^\nu(m)|a(n)\rangle
\]

\[
+ A_{\bar{\nu}(m)n}|s^\nu(m)|a(n)\rangle + A_{nm}|a(m)|a(n)\rangle + \cdots ,
\]

(20)

where the functions in the basis \( \cdots \) are already polarized and in fact present a
product structure in terms of the functions \( \{ \cdots \} \) that we are giving below; they
share a common weight function \( W \) depending on the representation:

\[
|0\rangle = \zeta W ,
\]

\[
|l^\mu(m)\rangle = \zeta W\{ l^\mu(m)\} ,
\]

\[
|s^\nu(m)\rangle = \zeta W\{ s^\nu(m)\} ,
\]

\[
|a(m)\rangle = \zeta W\{ a(m)\} ,
\]

(21)

\[
|l^{\mu_1}(m_1) \cdots s^{\mu_i}(m_j) \cdots a(m_k)\cdots \rangle = \zeta W\{ l^{\mu_1}(m_1)\} \cdots \{ s^{\mu_i}(m_j)\} \cdots \{ a(m_k)\} \cdots .
\]

The explicit forms of the corresponding functions are,

\[
W = 1 - \sum_{n(m_f \geq 0)} \left( \frac{1}{2} C_{\nu(m)\mu(n)}^\rho|l^\mu(m)|l^\nu(n) + \frac{1}{2} C_{mn}^\rho a(m)a(n)
\]

\[
+ C_{\mu(m)\bar{\nu}(n)}^\rho|l^\mu(m)|s^\nu(n) + C_{\mu(m)n}^\rho|l^\mu(m)|a(n) + \cdots \right) ,
\]
\{f^\gamma(q)\} = f^\gamma(q) - \sum_{t_f \leq 0, m_f > 0, n_f > 0, m_f + n_f \geq q_f} \left[ \frac{1}{2} C_{\rho}(m) C_{\sigma}(n) \right] F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( - \sum_{r_f \leq 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( \sum_{r_f > 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right]

\{s^\gamma(q)\} = s^\gamma(q) - \sum_{t_f \leq 0, m_f > 0, n_f > 0, m_f + n_f \geq q_f} \left[ \frac{1}{2} C_{\rho}(m) C_{\sigma}(n) \right] F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( - \sum_{r_f \leq 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( \sum_{r_f > 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right]

\{a(q)\} = a(q) - \sum_{t_f \leq 0, m_f > 0, n_f > 0, m_f + n_f \geq q_f} \left[ \frac{1}{2} C_{\rho}(m) C_{\sigma}(n) \right] F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( - \sum_{r_f \leq 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) + \frac{1}{8} \left( \sum_{r_f > 0} C_{\rho}(r) C_{\sigma}(r) \right) F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right] F^\gamma(t) F^\sigma(t) \right]

(22)
The action of the starting algebra is implemented by the right-invariant vector fields in such a way that those vector fields with \( m_f \leq 0 \) act as raising operators and those with \( m_f > 0 \) are lowering operators. Finally, the explicit action of these right-invariant vector fields on the lowest-order functions of the reduced Hilbert space is

\[
\hat{X}_{a(t)_{(t_f \leq 0)}}^R |0\rangle = C_{a(n)}^\mu |a(n)\rangle + C_{a(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f \leq 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]

\[
\hat{X}_{s(t)_{(t_f \leq 0)}}^R |\gamma(q)\rangle = C_{s(n)}^\mu |q(n)\rangle + C_{s(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f > 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]

\[
\hat{X}_{a(t)_{(t_f \leq 0)}}^R |\nu(n)\rangle = C_{\nu(n)}^\mu |q(n)\rangle + C_{\nu(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f \leq 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]

\[
\hat{X}_{s(t)_{(t_f \leq 0)}}^R |\nu(n)\rangle = C_{s(t)_{\nu(n)}}^\mu |\nu(n)\rangle + \frac{1}{2} C_{s(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f > 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]

\[
\hat{X}_{s(t)_{(t_f \leq 0)}}^R |\nu(n)\rangle = C_{s(t)_{\nu(n)}}^\mu |\nu(n)\rangle + \frac{1}{2} C_{s(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f > 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]

\[
\hat{X}_{s(t)_{(t_f \leq 0)}}^R |\nu(n)\rangle = C_{s(t)_{\nu(n)}}^\mu |\nu(n)\rangle + \frac{1}{2} C_{s(n)}^{\nu} |\nu(n)\rangle
\]

\[- \frac{1}{2} \sum_{r_f > 0} C_{\mu(n)}^{\nu(r)} C_{\nu(n)}^\rho \hat{a}(n) l^\mu(m) + \cdots ,
\]
\[
\tilde{X}^R_{I}(t_f \leq t) | 0 \rangle = C^\circ_{\tau(t)\nu(n)} | l^\nu(n) \rangle + C^\circ_{\tau(t)\rho(n)} | s^\nu(n) \rangle + C^\circ_{\tau(t)n} | a(n) \rangle \\
\quad - \sum_{r_f \leq 0} \left( \frac{1}{4} C_{\tau(t)\nu(n)} C_{\mu(m)\rho(r)} C^\circ_{\rho(r)} + \frac{1}{2} C^\circ_{\tau(t)\nu(n)} C_{\mu(m)\rho(r)} | l^\nu(n) l^\mu(m) \rangle \right) \\
\quad - \sum_{r_f \leq 0} C^\circ_{\tau(t)\rho(n)} C_{\mu(m)\rho(r)} | s^\nu(n) l^\mu(m) \rangle + \frac{1}{2} \sum_{r_f \leq 0} C^\circ_{\tau(t)n} C_{\mu(m)\rho(r)} | a(n) l^\mu(m) \rangle + \cdots,
\]

\[

\quad + \sum_{r_f \leq 0} \left( C^\circ_{\rho(r)\tau(t)\mu(m)\nu(n)} | l^\mu(m) s^\nu(n) \rangle \right) + \cdots,
\]
Extended Diffeomorphism Algebras in (Quantum) Gravitational Physics

\[
\hat{X}^R_{t_i(t_f \leq 0)} [a(q)] = C^q_{\tau(t)\mu(n)} [a(n)] + C^q_{\tau(t)\nu(n)} [l^\nu(n)a(q)] + \frac{1}{2} C^q_{\tau(t)\mu(n)} [s^\nu(n)a(q)] \\
+ C^q_{\tau(t)\mu(n)} [a(n)a(q)] - \sum_{r_f \leq 0} C^q_{\tau(t)\mu(n)} C^q_{\mu(m)r} [a(n)l^R(m)] + \cdots ,
\]

\[
\hat{X}^R_{a(t)(t_f > 0)} |0\rangle = 0 ,
\]

\[
\hat{X}^R_{a(t)(t_f > 0)} |a(q)\rangle = \delta(q - t)|0\rangle ,
\]

\[
\hat{X}^R_{a(t)(t_f > 0)} |l^\gamma(q)\rangle = 0 ,
\]

\[
\hat{X}^R_{a(t)(t_f > 0)} |s^\gamma(q)\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |0\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |a(q)\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |l^\gamma(q)\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |s^\gamma(q)\rangle = \delta_2^2 \delta(q - t)|0\rangle ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |0\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |a(q)\rangle = 0 ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |l^\gamma(q)\rangle = \delta_2^2 \delta(q - t)|0\rangle ,
\]

\[
\hat{X}^R_{s^\gamma(t)(t_f > 0)} |s^\gamma(q)\rangle = 0 ,
\]

where |0\rangle behaves as a vacuum state and is unique by construction. The action on higher-order functions is limited by the initial perturbative development in the group law. Apart from that, its computation is completely straightforward, though highly tedious.

As stated in the introduction, the Hilbert product \( \langle \cdots | \cdots \rangle \) is introduced by imposing \(|0\rangle|0\rangle = 1\) and specifying the adjoint operator for each one. In order to do so, we set the notation

\[
\hat{L}_\mu(m) = \hat{X}^R_{\mu^\mu(m)}, \quad \hat{A}(m) = \hat{X}^R_{a(m)}, \quad \hat{S}^\rho(m) = \hat{X}^R_{s^\rho(m)},
\]

and establish the corresponding adjoint operators

\[
\hat{L}_\mu^\dagger(m) = \hat{L}_\mu(-m), \quad \hat{A}^\dagger(m) = \hat{A}(-m), \quad (\hat{S}^\rho)^\dagger(m) = \hat{S}^\rho(-m).
\]

An immediate consequence of imposing positivity on the scalar product is an actual restriction on the possible values of the central extension parameters \( c, C^\rho, \tilde{C}_\rho \), which would be the higher-dimensional analogues to the conditions on \( (c, h) \) in the Virasoro algebra case. In particular, lower bounds for \( C^\rho, \tilde{C}_\rho \) must exist, since
they generalize $c$, $h$. More generally, an exhaustive analysis of unitarity and/or irreducibility can be accomplished by finding the algebraic conditions (which would generalize the Kac determinant formula) for the existence of higher-order polarizations. This can be achieved by following identical steps to those given for the Virasoro group in Ref. 19. Higher-order polarizations techniques guarantee irreducibility as they trivialize null-vector states.

4. Physical Interpretation

As mentioned in the Introduction, in the higher-dimensional case, we no longer have the connection with Physics provided by the Polyakov action. Consequently, we have not developed the analysis of the semi-classical situation nor constructed a Lagrangian, limiting ourselves to the presentation of the Noether invariants defining the symplectic structure. Therefore, the link between the abstract group parameters and the metric ingredients, needed to make contact with a gravitational theory, is less obvious. In fact, the present model is more properly interpreted as a kind of topological theory, though with local degrees of freedom, where a metric notion must be recovered by imposing a constraint (in the spirit of General Relativity from BF theory\textsuperscript{20–22}) or by adding an extra structure.

Here, we present different situations framed in a gravitational setting where the mathematical construction we have developed plays a significant role.

\textit{Space–time with boundary conditions}

Perhaps the most conservative application of the mathematical formalism developed in the previous section takes place in the context of standard General Relativity when boundary conditions play a significant role. The study of the solution space of the (classical) theory in these scenarios shows that, due to these conditions, some of the diffeomorphisms are not generated by the constraints of the theory\textsuperscript{23} and therefore the former are not gauge transformations. Consequently, they actually move the solution space and constitute a dynamical symmetry. In fact, in some models, such as asymptotic Anti-de Sitter solutions to $2+1$ gravity,\textsuperscript{24,25} which can be treated as a Chern–Simons theory, or some treatments of black-hole entropy,\textsuperscript{26} these diffeomorphisms parametrize the phase space of the theory providing the physical degrees of freedom. This identification of the solution space is a crucial first step for the quantization of the theory.

Abstract models for diffeomorphism dynamics such as the one presented above could prove to be useful in situations where the presence of more general boundary conditions confers a dynamical content to other subgroups of the diffeomorphism symmetry. We cannot avoid the impression that the limits in the application of these kind of techniques to more general scenarios is more related to our poor technical skills beyond the Virasoro symmetry than to actual conceptual problems.
Hilbert space of a gravitational theory

In the construction of a dynamical system out of a symmetry at the (semi-)classical level, there is a fundamental difference between the GAQ and, for instance, a more standard coadjoint orbits method. In fact, the former provides not only a symplectic structure on which dynamics can be described, but also determines the Hamiltonian function(s) which specifies the evolution of the system. In this sense, our topological model is endowed with intrinsic dynamics dictated by the vector fields in the characteristic module $G_\Theta$.

Nevertheless, we do not need the full structure of GAQ to formulate well-defined models. We can resort to the GAQ as a powerful method to obtain, out of a fundamental symmetry, a well-defined phase space on which dynamics are introduced by supplementing some extra information.

In this spirit, we are going to look at the quantum representation space of the previous section as the Hilbert space for a genuine quantum gravitational theory. In this sense, our mathematical construction supplies the kinematics of such a Gravity model. The relevance of this Hilbert space for a gravitational theory relies on the fact that the operators $L^\mu_\mu(m)$ and $L_\mu(m)$ essentially constitute a quantum realization of the vector fields with support on a manifold $M$. Taking advantage of the fact that a classical metric field is a symmetric $(0, 2)$ tensor field characterized by its action on such vector fields, we are introducing a quantum metric operator $\hat{g}$ by defining its action on some appropriate states ("quantized vector fields" on a manifold). An appropriate set of vector fields is the one defining a tetrad basis $\{e_a\}$. Considering the components of these tetrads in a coordinate basis and formally expanding them in plane-waves, we find

$$e_a(x) = e^\mu_a(x)\partial_\mu = \sum_m e^\mu_a(m)e^{im\cdot x^\rho}\partial_\mu = \sum_m ie^\mu_a(m)L_\mu(m), \quad (26)$$

where we have made used of the notation introduced in Subsec. 2.2. Thus, we promote the classical field $L_\mu(m)$ to a quantum operator by using the representation constructed in Sec. 3,

$$e_a \mapsto \hat{e}_a = \sum_m ie^\mu_a(m)\hat{L}_\mu(m). \quad (27)$$

Associating each of these operators with a canonical state, $|e_a\rangle \equiv \hat{e}_a|0\rangle$, we construct a metric operator $\hat{g}$ by imposing the quantum tetrad condition,

$$\langle e_a|\hat{g}|e_b\rangle = \eta_{ab}. \quad (28)$$

A minimal manner (in the sense that more general approaches could be followed) of implementing this condition consists in restricting the domain of the operator $\hat{g}$ to one-particle states $L^\mu_\mu(m)|0\rangle$. Even more, we demand it to be Hermitian ($\hat{g}^\dagger = \hat{g}$) and diagonal on the $m$ label of these states: $\hat{g}L^\mu_\mu(m)|0\rangle = g^\mu_\mu(m)L^\mu_\mu(m)|0\rangle$. For comparisons with the classical theory, it is better to introduce an object covariant
in the two space–time indices, \( g_{\mu\nu}(m) \equiv \langle 0 | L_\mu(m) \hat{g} L_\nu(m) | 0 \rangle \), whose explicit form is
\[
g_{\mu\nu}(m) = -\frac{C_\rho}{2} \left( g^\rho_\mu(m) (m \nu \delta^\rho_\sigma + m \sigma \delta^\rho_\nu) + g^\rho_\nu(m) (m \mu \delta^\rho_\sigma + m \sigma \delta^\rho_\mu) \right), \tag{29}
\]
where we have considered for simplicity that the only nonvanishing central parameter in (9) is \( C_\rho \). With these elements, condition (28) simply expresses:
\[
\eta_{ab} = \sum_m g_{\mu\nu}(m) e^\mu_a(m) e^{\nu*}_b(m), \tag{30}
\]
which is the analogue in this simplified example to the standard space–time variables expression and relates the quantum action of \( \hat{g} \) with a metric notion.

The connection with the classical theory can be achieved by reversing the step \( L_\mu(m) \rightarrow \hat{L}_\mu(m) \), and taking the parameters \( g_{\mu\nu}(m) \) as the Fourier components of the classical metric field:
\[
g_{\mu\nu}(x) = \sum_m e^{im_\mu x^\rho} g_{\mu\nu}(m). \tag{31}
\]
As stated above, the foregoing discussion describes the kinematics of the metric degrees of freedom, but offers no clue on the way in which the specific \( g_{\mu\nu}(m) \) (or \( e^\mu_a(m) \)) should be chosen. This is a dynamical information that will be added in this approach by imposing a constraint, external to the group, on the \( g_{\mu\nu}(m) \) parameters. The simplest one we can imagine, having a straightforward link to classical physics, is the Fourier transform of Einstein equations in vacuum, \( R_{\mu\nu} = 0 \). We find,
\[
0 = m_\lambda \sum_m g^{\lambda\sigma}(m - n)(n_\nu g_{\mu\sigma}(n) + n_\mu g_{\nu\sigma}(n) - n_{\sigma} g_{\mu\nu}(n))
\]
\[
- n_\nu \sum_n g^{\lambda\sigma}(m - n)(n_\lambda g_{\mu\sigma}(n) + n_\mu g_{\lambda\sigma}(n) - n_{\sigma} g_{\mu\nu}(n))
\]
\[
+ \sum_{n,p,q} g^{\rho\sigma}(m-n-p)(p_\nu g_{\rho\mu}(p) + p_\mu g_{\rho\nu}(p) - p_{\rho} g_{\nu\mu}(p))
\]
\[
\times g^{\lambda\sigma'}(n-q)(q_\lambda g_{\rho\sigma'}(q) + q_{\rho} g_{\lambda\sigma'}(q) - q_{\sigma'} g_{\lambda\eta}(q))
\]
\[
- \sum_{n,p,q} g^{\rho\sigma}(m-n-p)(p_\lambda g_{\rho\sigma}(p) + p_\sigma g_{\lambda\sigma}(p) - p_{\sigma} g_{\lambda\rho}(p))
\]
\[
\times g^{\lambda\sigma'}(n-q)(q_\rho g_{\nu\sigma'}(q) + q_{\nu} g_{\rho\sigma'}(q) - q_{\sigma'} g_{\rho\eta}(q)). \tag{32}
\]
A model where (a sector of) the quantum phase space is constructed out of the diffeomorphism modes corresponds to a theory where (parts of) the diffeomorphisms are not gauge transformations at the quantum level. We can then interpret the states in the Hilbert space as physical distortions of a reference space–time corresponding to the maximum weight vector in the representation. Therefore, \( |0\rangle \) would correspond to a locally flat space–time, where locally refers here to an entire
neighborhood, not simply to a point. One-particle states, which display a direct link with the quantized vector fields, would correspond to local excitations of the metric field in a given space–time direction, creating a distortion in distances measured by the action of the quantum operator $\hat{g}$. Even though the restricted definition of $\hat{g}$ to only the linear subspace of one-particle states is enough to show quantum features such as the probability transition between different metric excitation states, one can think of endowing multi-particle states also with the metric content. A simple way of extending the domain of $\hat{g}$ consists of defining a projector $P (P^2 = P)$ from the total representation Hilbert space to that of mono-particular states. Thus, we define $\hat{g}|\Psi\rangle \equiv \hat{g}P|\Psi\rangle$, so that an arbitrary state acquires a metric excitation interpretation.

Gauge gravity theories

In the GAQ, the group law of the starting symmetry comprises both the connection fields parameters and the ones corresponding to the local or gauge group itself. However, similarly to the electromagnetic case shown, a subtle nontrivial mixing between these two sets of parameters occurs, implying a restructuration of the gauge and physical degrees of freedom. As a result of this process, the original elements of the gauge group gain in fact a dynamical content. When we approach gravity by using local diffeomorphisms as the symmetry associated with local translations, the $l^\mu(m)$ parameters themselves acquire a metric meaning. Of course, the complete theory needs the addition of the other part of the group, something that in principle could be faced in different ways (directly metric structures, tetrad fields, Ashtekar connection variables...). However, regardless of the actual way in which this missing structure is introduced, combinations of $m_\mu \tilde{X}^R_r(m)$ will enter the theory as part of the physical gravitational degrees of freedom. Apart from that, the presence of new fields such as $S^\mu(m)$ in the extended diffeomorphism group, opens the possibility of constructing the matter side of the Einstein-like equations out of the symmetry structure. In the spirit of a gauge approach to Gravity, the construction in Sec. 3 should be understood as an intermediate step in the development of a yet-to-be-completed theory. Regarding the breakdown of diffeomorphism invariance, the presence of central terms in the commutator of the diffeomorphism generators turn them into a set of second-class constraints. Not all the spurious degrees of freedom can be eliminated, and thus, new physical modes appear. This is analogous to the emergence of Proca field in Ref. 5 or to the mechanism for cohomological mass generation of gauge bosons in Ref. 6. Finally, the secondary goal of advancing in the understanding of the interaction mixing is achieved by making explicit the nontrivial coupling of the diffeomorphisms and the local U(1) symmetry. In a general sense beyond the specific GAQ, the insight into diffeomorphism representations provided in Sec. 3 will help in the understanding of the imposition of diffeomorphism constraints in diffeomorphism invariant theories where a gauge is not fixed prior to quantization.
Phenomenological theories

The last physical interpretation promotes our construction to an effective theory valid at low-intermediate energies. An underlying more fundamental theory is assumed to exist at higher energies, with the only constraint that diffeomorphism invariance, as a gauge symmetry, must play a fundamental role in its formulation. Lacking such a description, though candidates do exist, a phenomenological one is proposed on two basic assumptions. On the one hand, the specific space-time dynamics are decoupled and described by the (semi-)classical theory (General Relativity or, more generally, Quantum Field Theory on curved spaces) and, on the other hand, the diffeomorphism invariance is anomalously realized in the quantum process which describes the implementation of the matter fields. This anomalous realization gives rise to effective deformations of the fundamental diffeomorphism algebra ($S^\mu(m)$ field) and confers a dynamical content to some of the, in principle spurious, gauge diffeomorphism degrees of freedom (the implementation of the diffeomorphism gauge invariance breakdown is explicit here). In this sense, the occurrence of an anomaly reveals the presence of more fundamental underlying physics at higher energies whose degrees of freedom are encoded at these intermediate energies in the emerging effective degrees of freedom.\(^{27}\) The particular model in this paper can be seen as a generalization to higher dimensions of the example presented in Ref. 28. This reference provides a more detailed description of the physics involved in this approach and suggests a mechanism for particle mass generation. Identifying $\hat{L}_\mu(0)$ with the Hamiltonian of the complete physical system, in a given coordinate system, and looking at the explicit form of its associated Noether invariant in terms of those ones corresponding to the physical degrees of freedom (see (16)), we find the general form

$$\hat{H}_{\text{eff}} = \hat{H}_{\text{free}}(\hat{\Phi}^\dagger, \hat{\Phi}) + \hat{H}_{\text{mixing}}(\hat{\Phi}^\dagger, \hat{\Phi}, (\hat{L}_\mu)^\dagger, \hat{L}_\mu, (\hat{F})^\dagger, \hat{F}),$$

where $\hat{\Phi}$ denote the nongravitational fundamental degrees of freedom (here $\hat{A}$, which can be seen as a scalar field), $\hat{L}_\mu$ are the dynamical diffeomorphisms and $\hat{F}$ are the extra anomalous effective degrees of freedom ($\hat{S}^\mu$ in our case). As we can see, the presence of such an anomaly entails corrections to the spectrum of the fundamental nongravitational degrees of freedom, opening the above-mentioned possibility of relating the emergence of mass terms to them. Finally, we must point out that, in contrast to the physical interpretation above that aimed at providing a gravitational Hilbert space, this phenomenological approach takes full advantage of the structures obtained with the GAQ. In fact, not only a representation space is constructed but also the dynamics is determined by the choice of the Hamiltonian among the generators inside $G_\Theta$.

5. Conclusions

The main result of the present work is the construction of a maximum-weight representation corresponding to the infinite-dimensional Lie algebra closed by the
local diffeomorphisms $L_\mu(m)$ defined on a manifold of dimension superior to one, acting in a semi-direct way on scalar modes $A(m)$ and finally noncentrally extended by the generator $S^\rho(m)$. Although these kinds of representations are already studied in Ref. 29, the singularity of ours is related to its explicit (nonformal) character and to the central role played by the concept of pseudo-cohomology. On the other hand, the choice of $S^\rho(m)$ for the noncentral extension fulfills the generalization of the mathematical structure in Ref. 1.

The physical relevance of this construction in the setting of (quantum) gravitational dynamics is exemplified by the discussion of several different approaches to the general problem. They all share the feature of conferring a privileged role to the notion of symmetry in the construction of the physical system. Our main conclusion is that the diffeomorphism group by itself cannot account for the complete gravitational dynamics (the basic aim in Ref. 1), since it basically defines a kind of topological theory. The latter needs to be supplemented with additional structure in order to account for standard metric notions, for instance, by including it into a larger group. However, this algebra proves to play a key role in the formulation of some nontrivial physical models for quantum gravity, where the issues of the breakdown of diffeomorphism invariance and the mixing with internal symmetries are raised. They suggest, in fact, some potential experimental consequences such as the presence of extra fields corresponding to noncentral extensions ($S^\rho$) or the corrections to nongravitational field propagators (phenomenological model).

It should be finally emphasized that the symmetry aspect here considered, i.e. the breaking down of the gauge character of diffeomorphisms, refers to properly quantum-mechanical gravitational phenomena, tied to topological properties of (quantum) space-time. Of course, standard metric dynamics should be included in a complete theory, which requires a larger symmetry structure, as commented above. In this sense, a line of current research attempts to identify vierbeins with sections in a jet-bundle group associated with the diffeomorphisms of space-time, which naturally includes the latter as a (classical) gauge group.

Acknowledgments

One of us, J. L. Jaramillo would like to thank the Mathematical Department of the Queen Mary and Westfield College (University of London), and specifically to Prof. S. Majid, for the hospitality during the development of part of the work.
